# Assigning Probabilities

Laplace's definition assumes that all outcomes are equally likely. Now we introduce a **more general definition** of probabilities that avoids this restriction.

- Let  $S$  be a sample space of an experiment with a finite number of outcomes. We assign a **probability  $p(s)$**  to each **outcome  $s$** , so that:
  - $0 \leq p(s) \leq 1$  for each  $s \in S$
  - $$\sum_{s \in S} p(s) = 1$$
- The function  $p$  from the set of all outcomes of the sample space  $S$  is called a ***probability distribution***.

# Assigning Probabilities

**Ex:** A trick coin is biased so that when flipped, the heads come up twice as often as tails. What probabilities should we assign to the outcomes  $H$  (heads) and  $T$  (tails) when the biased coin is flipped?

**Solution:** We are given that  $p(H) = 2p(T)$

Because  $p(H) + p(T) = 1$ , it follows that

$$2p(T) + p(T) = 3p(T) = 1.$$

Hence,  $p(T) = 1/3$  and  $p(H) = 2/3$ .

# Uniform Distribution

**Definition:** Suppose that  $S$  is a set with  $n$  elements. The *uniform distribution* assigns the probability  $1/n$  to each element of  $S$ . (Note that we could have used Laplace's definition here.)

**Example:** Consider again the coin flipping example, but with a *fair* coin. Now  $p(H) = p(T) = 1/2$ .

# Probability of an Event

**Definition:** The *probability* of the event  $E$  is the sum of the probabilities of the outcomes in  $E$ .

$$p(E) = \sum_{s \in E} p(s)$$

- Note that now no assumption is being made about the distribution.

# Example

**Ex:** Suppose that a 6-sided die is biased so that 3 appears twice as often as each other number, but that the other five outcomes are equally likely. What is the **probability that an odd number appears** when we roll this die?

**Solution:** We want the probability of the event  $E = \{1,3,5\}$ .

We have  $p(3) = 2/7$  and

$$p(1) = p(2) = p(4) = p(5) = p(6) = 1/7.$$

$$\begin{aligned} \text{Hence, } p(E) &= p(1) + p(3) + p(5) = \\ &1/7 + 2/7 + 1/7 = 4/7. \end{aligned}$$

# Probabilities of Complements and Unions of Events

- **Complements:**  $p(\overline{E}) = 1 - p(E)$  still holds. Since each outcome is in either  $E$  or  $\overline{E}$ , but not both,

$$\sum_{s \in S} p(s) = 1 = p(E) + p(\overline{E}).$$

- **Unions:**  $p(E_1 \cup E_2) = p(E_1) + p(E_2) - p(E_1 \cap E_2)$  also still holds under the new definition.

# Combinations of Events

**Theorem:** If  $E_1, E_2, \dots$  is a sequence of pairwise disjoint events in a sample space  $S$ , then

$$p\left(\bigcup_i E_i\right) = \sum_i p(E_i)$$

*see Exercises 36 and 37 for the proof*

# Conditional Probability

Events can be dependent, which means they can be affected by previous events

**Definition:** Let  $E$  and  $F$  be events with  $p(F) > 0$ . The **conditional probability of  $E$  given  $F$** , denoted by  $P(E|F)$ , is defined as:

$$p(E|F) = \frac{p(E \cap F)}{p(F)}$$

# Conditional Probability

**Ex:** A bit string of length four is generated at random so that each of the 16 bit strings of length 4 is equally likely. What is the probability that it contains at least two consecutive 0s, **given that** its first bit is a 0?

**Solution:** Let  $E$  be the event that the bit string contains at least two consecutive 0s, and  $F$  be the event that the first bit is a 0.

- Since  $E \cap F = \{0000, 0001, 0010, 0011, 0100\}$ ,  $p(E \cap F) = 5/16$ .
- Because 8 bit strings of length 4 start with a 0,  $p(F) = 8/16 = 1/2$ .

Hence,

$$p(E|F) = \frac{p(E \cap F)}{p(F)} = \frac{5/16}{1/2} = \frac{5}{8}.$$

# Conditional Probability

**Ex:** What is the conditional probability that a family with two children has two boys, **given that** they have at least one boy. Assume that each of the possibilities  $BB$ ,  $BG$ ,  $GB$ , and  $GG$  is equally likely (where  $B$  represents a boy and  $G$  represents a girl).

**Solution:** Let  $E$  be the event that the family has two boys and let  $F$  be the event that the family has at least one boy.

- Then  $E = \{BB\}$ ,  $F = \{BB, BG, GB\}$ ,
- $E \cap F = \{BB\}$ .
- It follows that  $p(F) = 3/4$  and  $p(E \cap F) = 1/4$ .

Hence,

$$p(E|F) = \frac{p(E \cap F)}{p(F)} = \frac{1/4}{3/4} = \frac{1}{3}.$$

# Independence

Events can be independent, which means the occurrence of one event gives no information about the probability of another event. That is,

- $p(E|F) = p(E)$
- $p(F)$  has no impact on  $p(E|F)$

**Definition:** The events  $E$  and  $F$  are **independent** if and only if

$$p(E \cap F) = p(E)p(F).$$

# Independence

**Ex:** Suppose  $E$  is the event that a randomly generated bit string of length four begins with a 1 and  $F$  is the event that this bit string contains an even number of 1s. **Are  $E$  and  $F$  independent** if the 16 bit strings of length four are equally likely?

**Solution:** There are 8 bit strings of length four that begin with a 1, and 8 bit strings of length four that contain an even number of 1s.

- Since the number of bit strings of length 4 is 16,

$$p(E) = p(F) = 8/16 = 1/2.$$

- Since  $E \cap F = \{1111, 1100, 1010, 1001\}$ ,  $p(E \cap F) = 4/16 = 1/4$ .

We conclude that  $E$  and  $F$  **are independent**, because

$$p(E \cap F) = 1/4 = (1/2) (1/2) = p(E) p(F)$$

# Independence

**Ex:** Assume (as in the previous example) that each of the four ways a family can have two children ( $BB$ ,  $GG$ ,  $BG$ ,  $GB$ ) is equally likely. Are the events  $E$ , that a family with two children **has two boys**, and  $F$ , that a family with two children **has at least one boy**, independent?

**Solution:**

- $E = \{BB\}$ , so  $p(E) = 1/4$ .
- We saw previously that  $p(F) = 3/4$  and  $p(E \cap F) = 1/4$ .

The events  $E$  and  $F$  are not independent since

$$p(E) p(F) = 3/16 \neq 1/4 = p(E \cap F) .$$

# Pairwise and Mutual Independence

**Definition:** The events  $E_1, E_2, \dots, E_n$  are *pairwise independent* if and only if  $p(E_i \cap E_j) = p(E_i) p(E_j)$  for all pairs  $i$  and  $j$  with  $i \leq j \leq n$ .

- Any 2 pairs of events are independent.

**Definition:** The events are *mutually independent* if

$$p(E_{i_1} \cap E_{i_2} \cap \dots \cap E_{i_m}) = p(E_{i_1})p(E_{i_2}) \dots p(E_{i_m})$$

whenever  $i_j, j = 1, 2, \dots, m$  are integers with

$$1 \leq i_1 < i_2 < \dots < i_m \leq n \text{ and } m \geq 2.$$

- Any  $m$  events are independent.

# Bernoulli Trials

**Definition:** Suppose an experiment can have only two possible outcomes, *e.g.*, the flipping of a coin or the random generation of a bit.

- Each performance of the experiment is called a *Bernoulli trial*.
- One outcome is called a *success* and the other a *failure*.
- If  $p$  is the probability of success and  $q$  the probability of failure, then  $p + q = 1$ .
- Many problems involve determining the probability of  $k$  successes when an experiment consists of  $n$  mutually independent Bernoulli trials.

# Bernoulli Trials

**Ex:** A fair coin is flipped 3 times.  $p(H) = \frac{1}{2} = p(T)$ .

What is the probability that we get three, two, one, or no heads?

**Solution:** There are  $2^3 = 8$  possible outcomes.

$$p(\text{three heads}) = C(3,3) / 8 = 1/8$$

$$p(\text{two heads}) = C(3,2) / 8 = 3/8$$

$$p(\text{one head}) = C(3, 1) / 8 = 3/8$$

$$p(\text{zero heads}) = C(3, 0) / 8 = 1/8$$

TTT

# Bernoulli Trials

**Ex:** A fair coin ( $p(H)=p(T)=\frac{1}{2}$ ) is flipped 5 times. What is the probability that we get five, four, three, two, one, or no heads?

**Solution:** There are  $2^5 = 32$  possible outcomes.

$$p(\text{five heads}) = C(5, 5) / 32 = 1/32$$

$$p(\text{four heads}) = C(5, 4) / 32 = 5/32$$

$$p(\text{three heads}) = C(5, 3) / 32 = 10/32$$

$$p(\text{two heads}) = C(5, 2) / 32 = 10/32$$

$$p(\text{one head}) = C(5, 1) / 32 = 5/32$$

$$p(\text{zero heads}) = C(5, 0) / 32 = 1/32$$

# Bernoulli Trials

**Ex:** A coin is biased so that the probability of heads is  $2/3$ .  
What is the probability that **exactly four heads occur**  
when the coin is flipped **seven** times?

**Solution:** There are  $2^7 = 128$  possible outcomes.

- The number of ways four of the seven flips can be heads is  $C(7,4)$ .
- The probability of each of the outcomes is  $(2/3)^4(1/3)^3$  since the seven flips are independent.
- Hence, the probability that exactly four heads occur is  
 $C(7,4) (2/3)^4(1/3)^3 = 560/ 2187$ .

# Probability of $k$ Successes in $n$ Independent Bernoulli Trials.

**Theorem 2:** The probability of exactly  $k$  successes in  $n$  independent Bernoulli trials, with probability of success  $p$  and probability of failure  $q = 1 - p$ , is

$$C(n,k)p^kq^{n-k}.$$

**Proof:**

- The outcome of  $n$  Bernoulli trials is an  $n$ -tuple  $(t_1, t_2, \dots, t_n)$ , where each  $t_i$  is either  $S$  (success) or  $F$  (failure).
- The probability of each outcome of  $n$  trials consisting of  $k$  successes and  $n - k$  failures (in any order) is  $p^kq^{n-k}$ .
- Because there are  $C(n,k)$   $n$ -tuples of  $S$ 's and  $F$ 's that contain exactly  $k$   $S$ 's, the probability of  $k$  successes is  $C(n,k)p^kq^{n-k}$ .

# Probability of $k$ Successes in $n$ Independent Bernoulli Trials.

**Theorem 2:** The probability of exactly  $k$  successes in  $n$  independent Bernoulli trials, with probability of success  $p$  and probability of failure  $q = 1 - p$ , is

$$C(n, k)p^kq^{n-k}.$$

- We denote by  $b(k:n, p)$  the probability of  $k$  successes in  $n$  independent Bernoulli trials with  $p$  the probability of success. Viewed as a function of  $k$ ,  $b(k:n, p)$  is the *binomial distribution*. By Theorem 2,

$$b(k:n, p) = C(n, k)p^kq^{n-k}.$$

# Random Variables

**Definition:** A *random variable* is a **function** from the sample space of an experiment to the set of real numbers. That is, a random variable assigns a real number to each possible outcome.

- A random variable is a **function**. It is **not a variable**, and it is **not random**!
- In the late 1940s W. Feller and J.L. Doob flipped a coin to see whether both would use “random variable” or the more fitting “chance variable.” Unfortunately, Feller won and the term “random variable” has been used ever since.

# Random Variables

**Definition:** The *distribution* of a random variable  $X$  on a sample space  $S$  is the set of pairs  $(r, p(X = r))$  for all  $r \in X(S)$ , where  $p(X = r)$  is the probability that  $X$  takes the value  $r$ .

**Ex:** Suppose that a coin is flipped three times. Let  $X(t)$  be the **random variable** that equals the number of heads that appear when  $t$  is the outcome. Then  $X(t)$  takes on the following values:

$$X(HHH) = 3,$$

$$X(HHT) = X(HTH) = X(THH) = 2,$$

$$X(TTH) = X(THT) = X(HTT) = 1$$

$$X(TTT) = 0.$$

Each of the eight possible outcomes has probability  $1/8$ . So, the **distribution of  $X(t)$**  is  $p(X = 3) = 1/8$ ,  $p(X = 2) = 3/8$ ,  $p(X = 1) = 3/8$ , and  $p(X = 0) = 1/8$ .
