Greedy Method

Outline / Reading

- Greedy Method as a fundamental algorithm design technique
- Application to problems of:
 - Making change
 - Fractional Knapsack Problem (Ch. 5.1.1)
 - Task Scheduling (Ch. 5.1.2)
 - Minimum Spanning Trees (Ch. 7.3) [future lecture]

Greedy Method Technique

- The greedy method is a general algorithm design paradigm, built on the following elements:
 - configurations: different choices, collections, or values to find
 - objective function: a score assigned to configurations, which we want to either maximize or minimize
- Idea: make a greedy choice (locally optimal) in hopes it will eventually lead to a globally optimal solution.
- It works best when applied to problems with the greedy-choice property
 - a globally-optimal solution can always be found by a series of local improvements from a starting configuration.

Making Change

- Problem: A dollar amount to reach and a collection of coin amounts to use to get there.
 - configuration: A dollar amount yet to return to a customer plus the coins already returned
 - objective function: Minimize number of coins returned.
- Greedy solution: Always return the largest coin you can.
- Ex. 1: Coins are valued \$.32, \$.08, \$.01
 - Has the greedy-choice property, since no amount over \$.32 can be made with a minimum number of coins by omitting a \$.32 coin (similarly for amounts over \$.08, but under \$.32).
- Ex. 2: Coins are valued \$.30, \$.20, \$.05, \$.01
 - Does not have greedy-choice property, since \$.40 is best made with two \$.20's, but the greedy solution will pick three coins (which ones?)

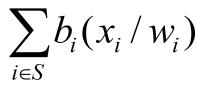

Fractional Knapsack Problem

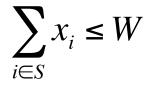

- Given: A set S of n items, with each item i having
 - $-b_i$ a positive benefit
 - w_i a positive weight
- Goal: Choose items with maximum total benefit but with weight at most *W*.

If we are allowed to take fractional amounts, then this is called the fractional knapsack problem.

- In this case, we let x_i denote the amount we take of item *i*
- objective: maximize

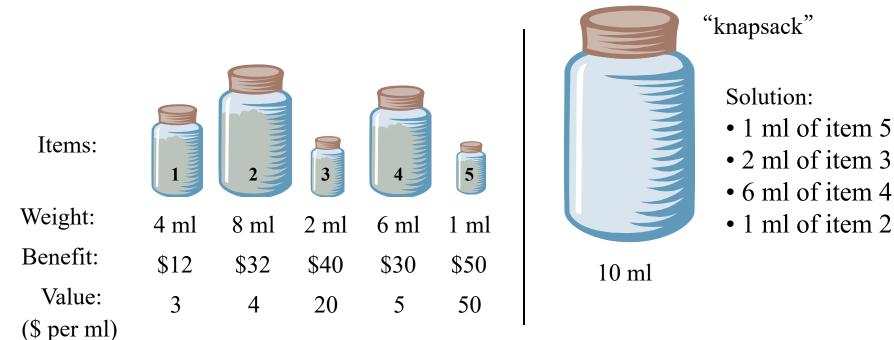

• constraint:

Example

- Given: A set S of n items, with each item i having
 - $-b_i$ a positive benefit
 - w_i a positive weight
- Goal: Choose items with maximum total benefit but with weight at most *W*.

Fractional Knapsack Algorithm

Greedy choice: Keep taking item with highest **value** (benefit to weight ratio)

- Since $\sum b_i(x_i / w_i) = \sum (b_i / w_i) x_i$
- Run time: $O(n \log n)$. Why?

Correctness:

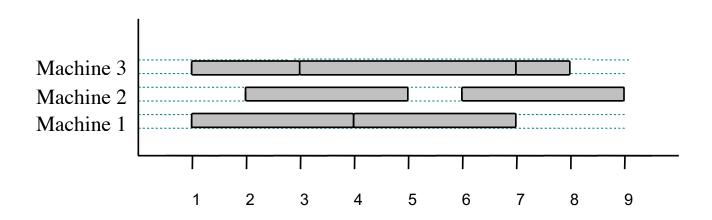

Suppose there is a optimal solution S* better than our greedy solution S.

- There is an item *i* in S with higher value than a chosen item *j* from S*, i.e., $v_i > v_j$ but $x_i < w_i$ and $x_j > 0$.
- If we substitute some *i* with *j*, we get a better solution in S*, a contradiction
 - How much of *i*: min{ w_i - x_i , x_j }
- Thus, there is no better solution than the greedy one

Algorithm *fractionalKnapsack*(*S*, *W*) **Input:** set **S** of items w/ benefit b_i and weight w_i ; max. weight W**Output:** amount x_i of each item *i* to maximize benefit with weight at most W for each item i in S $x_i \leftarrow 0$ $v_i \leftarrow b_i / w_i$ {value} $w \leftarrow 0$ {total weight} while w < Wremove item *i* with highest v_i $x_i \leftarrow \min\{w_i, W - w\}$ $w \leftarrow w + x_i$

Task Scheduling

- Given: a set *T* of *n* tasks, each having:
 - A start time, s_i
 - A finish time, f_i (where $s_i < f_i$)
- Goal: Perform all the tasks using a minimum number of "machines."

Tasks: [3,7] [1,4] [1,3] [4,7] [6,9] [7,8] [2,5]

Task Scheduling Algorithm

Greedy choice: consider tasks by their start time and use as few machines as possible with this order.

• Run time: O(n log n). Why?

Correctness:

Suppose there is a better schedule.

- We can use *k*-1 machines
- The algorithm uses k
- Let *i* be first task scheduled on machine *k*
- Task *i* must conflict with *k-1* other tasks
- But that means there is no nonconflicting schedule using *k-1* machines

Algorithm *taskSchedule*(*T*)

Input: set *T* of tasks w/ start time s_i and finish time f_i

Output: non-conflicting schedule with minimum number of machines

 $m \leftarrow 0$ {no. of machines}

while *T* is not empty

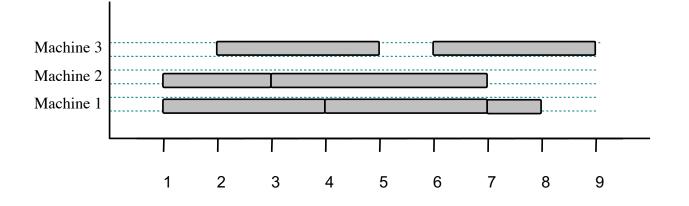

remove task i w/ smallest s_i if there 's a machine j for i then schedule i on machine j

else

 $m \leftarrow m + 1$ schedule i on machine m

Example

- Given: a set T of n tasks, each having:
 - A start time, s_i
 - A finish time, f_i (where $s_i < f_i$)
 - [1,4], [1,3], [2,5], [3,7], [4,7], [6,9], [7,8] (ordered by start)
- Goal: Perform all tasks on min. number of machines

Other

- The university has *n* classes it needs to schedule, using the minimum number of rooms possible.
 - Each class has a start/end time.
 - Each class should have at least 15 minutes between when one class ends in that room to when another class begins in the same room.
